

# SPECTRAL LOCALIZATION IN THE HIERARCHICAL ANDERSON MODEL

EVGENIJ KRITCHEVSKI

**ABSTRACT.** We prove that a large class of hierarchical Anderson models with spectral dimension  $d \leq 2$  has only pure point spectrum.

## 1. INTRODUCTION

This paper is devoted to study of the spectral properties of the hierarchical Anderson model and is motivated by the work of Molchanov [M2]. Before stating our results we recall the definition of the model and its basic properties. For additional information about the hierarchical structures and the hierarchical Anderson model we refer the reader to [D, BS, Bo, M1, M2].

Let  $X$  be an infinite countable set. Throughout the paper  $\delta_x$  will denote the Kronecker delta function at  $x \in X$ . A partition  $\mathcal{P}$  of  $X$  is a collection of its disjoint subsets whose union is equal to  $X$ . Let  $\mathbf{n} = (n_r)_{r \geq 0}$  be a sequence of positive integers and  $\mathbf{P} = (\mathcal{P}_r)_{r \geq 0}$  a sequence of partitions of  $X$ . The elements of  $\mathcal{P}_r$  are called "clusters" of rank  $r$ . We say that  $(X, \mathbf{P}, \mathbf{n})$  is a hierarchical structure if the following hold:

- (1)  $n_0 = 1$  and every  $Q \in \mathcal{P}_0$  has exactly one element.
- (2) For  $r \geq 1$ , every  $Q \in \mathcal{P}_r$  is a disjoint union of  $n_r$  clusters in  $\mathcal{P}_{r-1}$ .
- (3) Given  $x, y \in X$ , there is a cluster  $Q$  of some rank containing both  $x$  and  $y$ .

Let us state some immediate consequences of this definition. Every cluster of rank  $r \geq 0$  has size  $N_r := \prod_{s=0}^r n_s$ . Given  $x \in X$  and  $r \geq 0$ , there is a unique cluster of rank  $r$  containing  $x$ . We denote this cluster by  $Q_r(x)$ . The map

$$d(x, y) := \min \{r : y \in Q_r(x)\},$$

is a metric on  $X$  and  $Q_r(x) = \{y : d(x, y) \leq r\}$ . Note that  $Q_r(x) = Q_r(y)$  whenever  $d(x, y) \leq r$ . Given an integer  $n \geq 2$ , a hierarchical structure is called *homogeneous of degree  $n$*  if  $n_r = n$  for all  $r \geq 1$ .

The free Laplacian on the hierarchical structure  $(X, \mathbf{P}, \mathbf{n})$  is defined as follows. For each  $r \geq 0$ , let  $E_r : l^2(X) \rightarrow l^2(X)$  be the averaging operator

$$(E_r \psi)(x) := \frac{1}{N_r} \sum_{d(x,y) \leq r} \psi(y).$$

This work was supported in part by an FQRNT grant.

Let  $\mathbf{p} = (p_r)_{r \geq 1}$  be a sequence of positive numbers such that  $\sum_{r=1}^{\infty} p_r = 1$ . In the sequel we set  $p_0 := 0$  and

$$\lambda_r := \sum_{s=0}^r p_s, \quad r = 0, 1, \dots, \infty.$$

The hierarchical Laplacian  $\Delta$  on  $l^2(X)$  is defined by

$$\Delta := \sum_{r=0}^{\infty} p_r E_r.$$

Clearly,  $\Delta$  is a bounded self-adjoint operator and  $0 \leq \Delta \leq 1$ .

A hierarchical model is a hierarchical structure  $(X, \mathbf{P}, \mathbf{n})$  together with the hierarchical Laplacian  $\Delta$ . The spectral properties of  $\Delta$  only depend on  $\mathbf{n}$  and  $\mathbf{p}$  and are summarized in:

**Theorem 1.1.** (1) *The spectrum of  $\Delta$  is equal to  $\{\lambda_r : r = 0, \dots, \infty\}$ . Each  $\lambda_r$ ,  $r < \infty$ , is an eigenvalue of  $\Delta$  of infinite multiplicity. The point  $\lambda_{\infty} = 1$  is not an eigenvalue.*

(2)  *$E_r - E_{r+1}$  is the orthogonal projection onto the eigenspace of  $\lambda_r$  and*

$$\Delta = \sum_{r=0}^{\infty} \lambda_r (E_r - E_{r+1}).$$

(3) *For every  $x \in X$ , the spectral measure for  $\delta_x$  and  $\Delta$  is given by*

$$\mu = \sum_{r=0}^{\infty} \left( \frac{1}{N_r} - \frac{1}{N_{r+1}} \right) \delta(\lambda_r),$$

where  $\delta(\lambda_r)$  stands for the Dirac unit mass at  $\lambda_r$ . Note that  $\mu$  does not depend on  $x$ .

The spectral measure  $\mu$  can be naturally interpreted as the integrated density of states of the operator  $\Delta$ . Let  $x_0 \in X$  be given and consider the increasing sequence of clusters  $Q_r(x_0)$ ,  $r \geq 0$ . Let  $P_r$  be the orthogonal projection onto the  $N_r$ -dimensional subspace

$$l^2(Q_r(x_0)) := \{\psi \in l^2(X) : \psi(x) = 0 \text{ for } x \notin Q_r(x_0)\}.$$

Let  $e_1^{(r)} \leq e_2^{(r)} \leq \dots \leq e_{N_r}^{(r)}$  be the eigenvalues of the restricted Laplacian  $P_r \Delta P_r$  acting on  $l^2(Q_r(x_0))$  and

$$\nu_r := \frac{1}{N_r} \sum_{s=1}^r \delta(e_s^{(r)}),$$

the corresponding counting measure.

**Proposition 1.2.** *The weak-\* limit  $\lim_{r \rightarrow \infty} \nu_r$  exists and is equal to  $\mu$ .*

If

$$\lim_{t \downarrow 0} \frac{\log \mu([1-t, 1])}{\log t} = d/2,$$

then the number  $d$  is called the *spectral dimension* of  $\Delta$ . This definition is motivated by the analogy with the edge asymptotics of the density of states of the standard discrete Laplacian on  $\mathbb{Z}^d$ , for which the spectral and spatial dimensions coincide.

The relation  $\sum_{y \in X} \langle \delta_x | \Delta \delta_y \rangle = 1$  yields that  $\Delta$  generates a random walk on  $X$ . We recall that the random walk on  $\mathbb{Z}^d$  generated by the standard discrete

Laplacian is recurrent if  $d = 1, 2$  and transient if  $d > 2$ . The corresponding result for the hierarchical Laplacian is:

**Proposition 1.3.** *Consider a homogeneous hierarchical structure of degree  $n \geq 2$ . Suppose that there exist constants  $C_1 > 0, C_2 > 0$  and  $\rho > 1$  such that*

$$C_1\rho^{-r} \leq p_r \leq C_2\rho^{-r},$$

for  $r$  big enough. Then:

(1) The spectral dimension of this model is

$$d(n, \rho) = 2 \frac{\log n}{\log \rho}.$$

Hence  $0 < d(n, \rho) \leq 2$  iff  $n \leq \rho$ .

(2) The random walk generated by  $\Delta$  is recurrent if  $0 < d(n, \rho) \leq 2$  and transient if  $d(n, \rho) > 2$ .

We now define the hierarchical Anderson model associated to  $(X, \mathbf{P}, \mathbf{n})$  and the hierarchical Laplacian  $\Delta$ . Consider the probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  where  $\Omega := \mathbb{R}^X$ ,  $\mathcal{F}$  is the usual Borel  $\sigma$ -algebra in  $\Omega$ , and  $\mathbb{P}$  is a given probability measure on  $(\Omega, \mathcal{F})$ . For  $\omega \in \Omega$ , we set

$$V_\omega := \sum_{x \in X} \omega(x) \langle \delta_x | \cdot \rangle \delta_x.$$

$V_\omega$  is a self-adjoint (possibly unbounded) multiplication operator on  $l^2(X)$ . Let

$$H_\omega := \Delta + V_\omega, \quad \omega \in \Omega.$$

The family of self-adjoint operators  $\{H_\omega\}_{\omega \in \Omega}$  indexed by the events of the probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  is called the *hierarchical Anderson model*.

Concerning the probability measure  $\mathbb{P}$ , we will need only one technical assumption having to do with the notion of conditional density. Throughout the paper,  $m$  will denote the Lebesgue measure on  $\mathbb{R}$ . For any  $x \in X$ ,  $\Omega$  can be decomposed along the  $x$ 'th coordinate as  $\Omega = \mathbb{R} \times \tilde{\Omega}$ ,  $\tilde{\Omega} = \mathbb{R}^{X \setminus \{x\}}$ . Let  $\tilde{\mathbb{P}}_x$  be the corresponding marginal of  $\mathbb{P}$  defined by  $\tilde{\mathbb{P}}_x(\tilde{B}) := \mathbb{P}(\mathbb{R} \times \tilde{B})$ , where  $\tilde{B} \subset \tilde{\Omega}$  is a Borel set. Then for  $\tilde{\mathbb{P}}_x$ -a.e.  $\tilde{\omega} \in \tilde{\Omega}$ , there is a probability measure  $\tilde{\mathbb{P}}_x^{\tilde{\omega}}$  on  $\mathbb{R}$  s.t. the conditional Fubini theorem holds: for all  $f \in L^1(\Omega, P)$  we have

$$\int_{\Omega} f(\omega) d\mathbb{P}(\omega) = \int_{\tilde{\Omega}} \left( \int_{\mathbb{R}} f(\xi, \tilde{\omega}) d\tilde{\mathbb{P}}_x^{\tilde{\omega}}(\xi) \right) d\tilde{\mathbb{P}}_x(\tilde{\omega}).$$

If for  $\tilde{\mathbb{P}}_x$ -a.e.  $\tilde{\omega} \in \tilde{\Omega}$ ,  $\tilde{\mathbb{P}}_x^{\tilde{\omega}}$  is absolutely continuous (a.c.) with respect to  $m$ , then we say that  $\mathbb{P}$  has a conditional density along the  $x$ 'th coordinate.  $\mathbb{P}$  is called conditionally a.c. if for every  $x \in X$ ,  $\mathbb{P}$  has a conditional density along the  $x$ 'th coordinate. An important special case of a conditionally a.c. probability measure is the product measure  $\mathbb{P} = \otimes_{x \in X} \mathbb{P}_x$ , where each  $\mathbb{P}_x$  is a probability measure on  $\mathbb{R}$  a.c. with respect to  $m$ .

We denote by  $\sigma_{\text{ac}}(H_\omega)$  the absolutely continuous part of the spectrum of  $H_\omega$  and by  $\sigma_{\text{cont}}(H_\omega)$  the continuous part. Our main result is:

**Theorem 1.4.** *Assume that there exists a sequence  $u_r > 0$  such that  $\sum_{r=1}^{\infty} u_r^{-1} < \infty$  and*

$$(1.1) \quad \sum_{r=1}^{\infty} p_r N_{r-1} u_{r-1} u_r < \infty.$$

Then:

- (1) For all  $\omega \in \Omega$ ,  $\sigma_{\text{ac}}(H_\omega) = \emptyset$ .
- (2) If  $\mathbb{P}$  is conditionally a.c. then  $\sigma_{\text{cont}}(H_\omega) = \emptyset$  for  $\mathbb{P}$ -a.e.  $\omega$ .

**Remark 1.** Theorem 1.4 and Proposition 1.3 allow to construct hierarchical models with spectral dimension  $d \leq 2$  that exhibit Anderson localization at arbitrary disorder. If  $(X, \mathbf{P}, \mathbf{n})$  is a homogeneous hierarchical structure of degree  $n \geq 2$  and  $p_r = C\rho^{-r}$  with  $\rho > n$ , then the hypothesis (1.1) is fulfilled for  $u_r = r^{1+\varepsilon}$ . Given  $0 < d < 2$ , one can adjust  $\rho > n$  to make  $d(n, \rho) = d$ . If  $p_r = Cr^{-3-\varepsilon}n^{-r}$ , then the model has spectral dimension  $d = 2$  and (1.1) is verified for  $u_r = r^{1+\varepsilon/3}$ . One can also construct trivial models with  $d = 0$  by taking  $p_r$  to decrease faster than  $\rho^{-r}$  for any  $\rho$ . We emphasize that homogeneity of the hierarchical structure is not required for Theorem 1.4.

**Remark 2.** In [M2], Molchanov has proven that if the random variables  $\omega(x)$  are i.i.d. with a Cauchy distribution, then Theorem 1.4 holds under the condition

$$\sum_{r=1}^{\infty} p_r u_r < \infty.$$

In particular, in this case the theorem holds for  $\Delta$  of any spectral dimension. Molchanov's argument is based on subtle properties of Cauchy random variables and cannot be directly extended to any other probability measure. In contrast, our proof of localization in spectral dimension  $d \leq 2$  is based on general arguments and is the first step in extending Molchanov's result to a more general class of probability measures.

**Remark 3.** The fractional moments method of Aizenman and Molchanov [AM] allows to prove localization for  $\Delta + \sigma V_\omega$  for large disorder  $\sigma$  or for large energies. One needs an extra decoupling hypothesis on the random variables  $\omega(x)$  and the condition on  $\Delta$  that

$$(1.2) \quad B := \sup_x \sum_{y \in X} |\langle \delta_x | \Delta \delta_y \rangle|^s < \infty$$

for some  $0 < s < 1$ . Simple estimates show that

$$\sum_{r=1}^{\infty} p_r N_r^{1-s} \leq B \leq \sum_{r=1}^{\infty} p_r^s N_r^{1-s}.$$

The requirement (1.2) on the decay of  $p_r$  is comparable to the hypothesis (1.1), while Theorem 1.4 is valid at arbitrary disorder or energy.

**Remark 4.** Part (2) of Theorem 1.4 does not hold for all  $\omega$ . Our method of proof combined with the general results of [DMS], [G] yields that  $H_\omega$  will have singular continuous spectrum for some  $\omega$ 's.

## 2. THE FREE LAPLACIAN

In this section, we prove Theorem 1.1, Proposition 1.2 and Proposition 1.3.

*Proof of Theorem 1.1.* For  $r \geq 0$ , let  $\mathcal{H}_r = \text{Ran}(E_r)$ .  $\mathcal{H}_r$  is the closed subspace of  $l^2(X)$  consisting of functions that are constant on each cluster of rank  $r$ . Note that

$$l^2(X) = \mathcal{H}_0 \supset \mathcal{H}_1 \supset \mathcal{H}_2 \supset \mathcal{H}_3 \supset \dots$$

and that  $\bigcap \mathcal{H}_r = \{0\}$  since a nonzero function constant on every cluster would have infinite  $l^2$  norm. These observations yield that

$$(2.1) \quad l^2(X) = \bigoplus_{r=0}^{\infty} L_r,$$

where  $L_r$  is the orthogonal complement of  $\mathcal{H}_{r+1}$  in  $\mathcal{H}_r$ . Note that  $L_r$  is the infinite dimensional subspace of functions  $\psi$  s.t.  $E_s\psi = \psi$  for  $0 \leq s \leq r$  and  $E_s\psi = 0$  for  $s > r$ . Hence for every  $\psi \in L_r$ ,  $\Delta\psi = \lambda_r\psi$ , and this proves parts (1) and (2).

The spectral measure  $\mu_{x,\Delta}$  for  $\delta_x$  and  $\Delta$  is the unique Borel probability measure on  $\mathbb{R}$  s.t.

$$\langle \delta_x | f(\Delta)\delta_x \rangle = \int_{\mathbb{R}} f(\xi) d\mu_{x,\Delta}(\xi),$$

for every bounded Borel function  $f : \mathbb{R} \rightarrow \mathbb{C}$ . To compute  $\mu_{x,\Delta}$ , we decompose  $\delta_x$  according to (2.1):

$$\delta_x = \sum_{r=0}^{\infty} (E_r - E_{r+1})\delta_x = \sum_{r=0}^{\infty} \left( \frac{1}{N_r} \mathbf{1}_{Q_r(x)} - \frac{1}{N_{r+1}} \mathbf{1}_{Q_{r+1}(x)} \right),$$

where  $\mathbf{1}_{Q_r(x)} := \sum_{y \in Q_r(x)} \delta_y$ . Hence

$$f(\Delta)\delta_x = \sum_{r=0}^{\infty} f(\lambda_r) \left( \frac{1}{N_r} \mathbf{1}_{Q_r(x)} - \frac{1}{N_{r+1}} \mathbf{1}_{Q_{r+1}(x)} \right),$$

and

$$\langle \delta_x | f(\Delta)\delta_x \rangle = \sum_{r=0}^{\infty} f(\lambda_r) \left\| \frac{1}{N_r} \mathbf{1}_{Q_r(x)} - \frac{1}{N_{r+1}} \mathbf{1}_{Q_{r+1}(x)} \right\|^2.$$

Since  $\left\| \frac{1}{N_r} \mathbf{1}_{Q_r(x)} - \frac{1}{N_{r+1}} \mathbf{1}_{Q_{r+1}(x)} \right\|^2 = 1/N_r - 1/N_{r+1}$ , (3) follows.  $\square$

The analysis of the density of states of  $\Delta$  is facilitated if one introduces the cut-off Laplacians

$$\Delta_r := \sum_{s=0}^r p_s E_s, \quad r \geq 0.$$

It is technically easier to work with  $\Delta_r$  than with  $P_r \Delta P_r$ . Note that  $l^2(Q_r(x_0))$  is an invariant subspace for  $\Delta_r$ . One can exactly compute the eigenvalues and eigenvectors of the restricted operator  $P_r \Delta_r$  acting on  $l^2(Q_r(x_0))$ . If  $0 \leq s \leq r$ , then every  $\psi \in L_s \cap l^2(Q_r(x_0))$  is an eigenvector of  $P_r \Delta_r$  with eigenvalue  $\lambda_r$ . The subspace  $L_s \cap l^2(Q_r(x_0))$  has dimension  $D_s^{(r)} := N_r(1/N_s - 1/N_{s+1})$  for  $0 \leq s \leq r-1$ , and the subspace  $L_r \cap l^2(Q_r(x_0))$  has dimension  $D_r^{(r)} := 1$ . Since  $\sum_{s=0}^r D_s^{(r)} = N_r$ , the spectrum of  $P_r \Delta_r$  is equal to  $\{\lambda_s : s = 0, \dots, r\}$  and each eigenvalue  $\lambda_s$  has multiplicity  $D_s^{(r)}$ .

*Proof of Proposition 1.3.* Let  $\nu^*$  be a weak-\* limit point of the sequence  $\nu_r$ . Let  $\nu_{r_k}$  be a subsequence converging to  $\nu^*$ . We claim that

$$(2.2) \quad \nu^*(\{\lambda_s\}) = \mu(\{\lambda_s\}),$$

for all  $s \geq 0$ . Indeed, let  $\delta := \min_{j \neq s} |\lambda_s - \lambda_j|/2$  and  $0 < \varepsilon < \delta/3$ . Since  $\|P_r \Delta P_r - P_r \Delta_r\| \leq \sum_{j=r+1}^{\infty} p_j$ , we have that  $\|P_r \Delta P_r - P_r \Delta_r\| \leq \varepsilon$  for all  $r$  big enough. For such  $r$ , the spectrum of  $P_r \Delta P_r$  is contained in  $\bigcup_{j=0}^r [\lambda_j - \varepsilon, \lambda_j + \varepsilon]$ . Let  $R$  be the spectral projection of  $P_r \Delta P_r$  on  $[\lambda_s - \varepsilon, \lambda_s + \varepsilon]$  and  $T$  the spectral

projection of  $P_r \Delta_r$  on the same interval. Let  $\gamma$  be the circle  $\{z \in \mathbb{C} : |z - \lambda_s| = \delta\}$ , oriented counterclockwise. Then

$$\begin{aligned} R - T &= \frac{1}{2\pi i} \oint_{\gamma} (z - P_r \Delta P_r)^{-1} dz - \frac{1}{2\pi i} \oint_{\gamma} (z - P_r \Delta_r)^{-1} dz \\ &= \frac{1}{2\pi i} \oint_{\gamma} (z - P_r \Delta P_r)^{-1} (P_r \Delta P_r - P_r \Delta_r) (z - P_r \Delta_r)^{-1} dz, \end{aligned}$$

and thus

$$\|R - T\| \leq \delta(2\delta/3)^{-1} \varepsilon(2\delta/3)^{-1} \leq 3/4 < 1.$$

It follows that  $Ran(R)$  and  $Ran(T)$  have the same dimension and that

$$\#\left\{s : e_s^{(r)} \in [\lambda_s - \varepsilon, \lambda_s + \varepsilon]\right\} = D_s^{(r)}.$$

Then for all  $k$  big enough

$$\nu_{r_k}([\lambda_s - \varepsilon, \lambda_s + \varepsilon]) = D_s^{(r)}/N_r = 1/N_s - 1/N_{s+1}.$$

Letting  $k \rightarrow \infty$ , we get  $\nu^*([\lambda_s - \varepsilon, \lambda_s + \varepsilon]) = 1/N_s - 1/N_{s+1}$ , and (2.2) follows by taking  $\varepsilon \downarrow 0$ . Since  $\sum_{s=0}^{\infty} (1/N_s - 1/N_{s+1}) = 1$  and  $\nu^*$  is a probability measure, we must have that  $\nu^* = \mu$ . Therefore  $\mu$  is the unique weak-\* limit point of the sequence  $\nu_r$  and  $\lim_{r \rightarrow \infty} \nu_r = \mu$ .  $\square$

*Proof of Proposition 1.3.* Note that  $\mu([1-t, 1])$  is a piecewise constant function of  $t$  with jump discontinuities at the points  $1 - \lambda_r$ . Since

$$C_1(\rho - 1)^{-1} \rho^{-r} \leq 1 - \lambda_r = \sum_{s=r+1}^{\infty} p_s \leq C_2(\rho - 1)^{-1} \rho^{-r},$$

and  $\mu([1 - \lambda_r, 1]) = 1/N_r = n^{-r}$ , we have that

$$\lim_{t \downarrow 0} \frac{\log \mu([1-t, 1])}{\log t} = \frac{\log n}{\log \rho},$$

which proves (1).

The random walk on  $X$  starting at  $x$  is transient if  $R := \sum_{k=0}^{\infty} \langle \delta_x | \Delta^k \delta_x \rangle < \infty$  and recurrent if  $R = \infty$ . Part (3) of Theorem 1.1 allows to compute  $R$  explicitly:

$$R = \langle \delta_x | (1 - \Delta)^{-1} \delta_x \rangle = \int \frac{d\mu(\xi)}{1 - \xi} = \sum_{r=0}^{\infty} \frac{N_r^{-1} - N_{r+1}^{-1}}{1 - \lambda_r}.$$

The bounds

$$C_2^{-1}(\rho - 1)(1 - 1/n) \sum_{r=0}^{\infty} (\rho/n)^r \leq R \leq C_1^{-1}(\rho - 1)(1 - 1/n) \sum_{r=0}^{\infty} (\rho/n)^r$$

show that  $R < \infty$  for  $\rho < n$  and  $R = \infty$  for  $\rho \geq n$ , and part (2) follows.  $\square$

### 3. PROOF OF THE LOCALIZATION THEOREM

This section is devoted to the proof of Theorem 1.4 and is organized as follows. We first derive a hierarchical approximation formula for the resolvent  $(H_{\omega} - z)^{-1}$ . Then we use the formula to obtain a bound on the resolvent matrix elements. This bound combined with the Simon-Wolff localization criterion yields the statement.

Set

$$H_{\omega, r} := V_{\omega} + \sum_{s=0}^r p_s E_s, \quad r \geq 0.$$

Fix  $\omega \in \Omega$ . For any  $Q_r \in \mathcal{P}_r$ , the subspace  $l^2(Q_r)$  is invariant for  $H_{\omega,r}$ . Let  $\sigma(\omega, Q_r)$  be the set of the eigenvalues of the restricted operator  $H_{\omega,r} \upharpoonright l^2(Q_r)$  and  $\sigma_\omega := \bigcup \sigma(\omega, Q_r)$  where the union is over all clusters of all ranks. Clearly,  $\sigma_\omega$  is a countable subset of  $\mathbb{R}$ . For  $z \in \mathbb{C} \setminus \sigma_\omega$ ,  $r \geq 0$ , and  $x, y \in X$ , we set

$$G_{\omega,r}(x, y; z) := \langle \delta_x | (H_{\omega,r} - z)^{-1} \delta_y \rangle.$$

For  $z \in \mathbb{C} \setminus \sigma_\omega$ ,  $r \geq 0$  and  $t \in X$ , let  $g_{\omega,r}(t; z)$  be the average of  $G_{\omega,r}(\cdot, t; z)$  over the cluster  $Q_r(t)$ , i.e.

$$g_{\omega,r}(t; z) := \frac{1}{N_r} \sum_{d(t', t) \leq r} G_{\omega,r}(t', t; z).$$

Since the joint spectral measure for  $\delta_t$ ,  $\delta_{t'}$  and  $H_{\omega,r}$  is real,  $G_{\omega,r}(t', t; z) = G_{\omega,r}(t, t'; z)$  and

$$(3.1) \quad g_{\omega,r}(t; z) = \frac{1}{N_r} \sum_{d(t', t) \leq r} G_{\omega,r}(t, t'; z) = \frac{1}{N_r} \langle \delta_t | (H_{\omega,r} - z)^{-1} \mathbf{1}_{Q_r(t)} \rangle.$$

**Proposition 3.1.** *Let  $\omega \in \Omega$ ,  $x, y \in X$ ,  $z \in \mathbb{C} \setminus \sigma_\omega$  and  $r \geq 0$  be given. Then*

$$(3.2) \quad G_{\omega,r}(x, y; z) = G_{\omega,0}(x, y; z) - \sum_{s=d(x,y)}^r p_s N_{s-1} g_{\omega,s-1}(x; z) g_{\omega,s}(y; z).$$

*Proof.* The formula holds for  $r = 0$  since  $p_0 = 0$ . For  $s \geq 1$ , the resolvent identity yields

$$(H_{\omega,s} - z)^{-1} \delta_y - (H_{\omega,s-1} - z)^{-1} \delta_y = -(H_{\omega,s-1} - z)^{-1} p_s E_s (H_{\omega,s} - z)^{-1} \delta_y.$$

Observe that  $E_s (H_{\omega,s} - z)^{-1} \delta_y = g_{\omega,s}(y; z) \mathbf{1}_{Q_s(y)}$ . Taking  $\langle \delta_x | \cdot \rangle$  in the above equation yields

$$(3.3) \quad G_{\omega,s}(x, y; z) - G_{\omega,s-1}(x, y; z) = -p_s g_{\omega,s}(y; z) \langle \delta_x | (H_{\omega,s-1} - z)^{-1} \mathbf{1}_{Q_s(y)} \rangle.$$

Note that by (3.1),

$$\langle \delta_x | (H_{\omega,s-1} - z)^{-1} \mathbf{1}_{Q_s(y)} \rangle = \begin{cases} N_{s-1} g_{\omega,s-1}(x; z), & \text{if } d(x, y) \leq s, \\ 0, & \text{if } d(x, y) > s. \end{cases}$$

The formula (3.2) follows after adding (3.3) for  $s = 1, 2, \dots, r$ .  $\square$

The key step in our proof is:

**Theorem 3.2.** *Suppose that  $p_r$  and  $N_r$  satisfy (1.1). Let  $\omega \in \Omega$  and  $x \in X$  be fixed. Then for m-a.e.  $e \in \mathbb{R} \setminus \sigma_\omega$ ,*

$$(3.4) \quad \sup_{r \geq 0} \sum_{y \in X} |G_{\omega,r}(x, y; e)|^2 < \infty.$$

*Proof.* We shall use the following general result, proven in [M2]:

Let  $A$  be a hermitian  $N \times N$  matrix and  $v \in \mathbb{C}^N$ . Then for all  $M > 0$ ,

$$(3.5) \quad m \left( \left\{ e : \| (A - e)^{-1} v \|_2^2 \geq M \right\} \right) \leq 4 \sqrt{\frac{N}{M}} \|v\|_2,$$

where  $\|\cdot\|_2$  stands for the  $l^2$  norm on  $\mathbb{C}^N$ .

Since  $l^2(Q_r(x))$  is an  $N_r$ -dimensional invariant subspace for  $H_{\omega,r}$  and since  $\|\mathbf{1}_{Q_r(x)}\|_2 = \sqrt{N_r}$ , we have from (3.5) that for  $M_r > 0$ ,

$$m \left( \left\{ e \in \mathbb{R} \setminus \sigma_\omega : \left\| (H_{\omega,r} - e)^{-1} \mathbf{1}_{Q_r(x)} \right\|_2^2 \geq M_r \right\} \right) \leq \frac{4N_r}{\sqrt{M_r}}.$$

Let  $M_r > 0$  be a sequence satisfying  $\sum_{r=1}^{\infty} N_r M_r^{-1/2} < \infty$ . By the Borel-Cantelli lemma, for  $m$ -a.e.  $e \in \mathbb{R} \setminus \sigma_\omega$ , there exists a finite constant  $C_e$  such that

$$(3.6) \quad \left\| (H_{\omega,r} - e)^{-1} \mathbf{1}_{Q_r(x)} \right\|_2^2 < C_e M_r,$$

for all  $r \geq 0$ . From now on, such an  $e \in \mathbb{R} \setminus \sigma_\omega$  is fixed. Using the representation formula (3.2), we get the estimate

$$(3.7) \quad \begin{aligned} \left( \sum_{y \in X} |G_{\omega,r}(x, y; e)|^2 \right)^{1/2} &\leq |G_{\omega,0}(x, x; e)| \\ &+ \sum_{s=1}^r p_s N_{s-1} |g_{\omega,s-1}(x; e)| \left( \sum_{d(x,y) \leq s} |g_{\omega,s}(y; e)|^2 \right)^{1/2}. \end{aligned}$$

Observe that

$$\begin{aligned} \left( \sum_{d(x,y) \leq s} |g_{\omega,s}(y; e)|^2 \right)^{1/2} &= \left( \sum_{d(x,y) \leq s} \left| \frac{1}{N_s} \langle \delta_y | (H_{\omega,s} - e)^{-1} \mathbf{1}_{Q_s(y)} \rangle \right|^2 \right)^{1/2} \\ &= \frac{1}{N_s} \left( \sum_{d(x,y) \leq s} |\langle \delta_y | (H_{\omega,s} - e)^{-1} \mathbf{1}_{Q_s(x)} \rangle|^2 \right)^{1/2} \\ &= \frac{1}{N_s} \left\| (H_{\omega,s} - e)^{-1} \mathbf{1}_{Q_s(x)} \right\|_2. \end{aligned}$$

Inequality (3.6) gives the bound

$$(3.8) \quad \left( \sum_{d(x,y) \leq s} |g_{\omega,s}(y; e)|^2 \right)^{1/2} \leq C_e^{1/2} \frac{\sqrt{M_s}}{N_s}.$$

Moreover

$$(3.9) \quad N_{s-1} |g_{\omega,s-1}(x; e)| = |\langle \delta_x | (H_{\omega,s-1} - e)^{-1} \mathbf{1}_{Q_{s-1}(x)} \rangle| \leq C_e^{1/2} \sqrt{M_{s-1}}.$$

Combination of (3.7) with (3.9) and (3.8) yields the estimate

$$\left( \sum_{y \in X} |G_{\omega,r}(x, y; e)|^2 \right)^{1/2} \leq |G_{\omega,0}(x, x; e)| + C_e \sum_{s=1}^r p_s \frac{\sqrt{M_s} \sqrt{M_{s-1}}}{N_s}.$$

By hypothesis (1.1), the sequence  $M_r = (u_r N_r)^2$  satisfies

$$\sum_{r=1}^{\infty} N_r M_r^{-1/2} = \sum_{r=1}^{\infty} u_r^{-1} < \infty.$$

Since

$$\sum_{r=1}^{\infty} p_r \frac{\sqrt{M_r} \sqrt{M_{r-1}}}{N_r} = \sum_{r=1}^{\infty} p_r N_{r-1} u_{r-1} u_r < \infty,$$

the result follows.  $\square$

Let us recall the Simon-Wolff localization criterion. For  $x \in X$  and  $\omega \in \Omega$ , denote by  $\mu_x^\omega$  the spectral measure for  $\Delta + V_\omega$  and  $\delta_x$ , by  $\mu_{x,\text{cont}}^\omega$  the continuous part of  $\mu_x^\omega$  and by  $\mu_{x,\text{ac}}^\omega$  the a.c. part. Define the function  $G_{\omega,x} : \mathbb{R} \rightarrow [0, +\infty]$  by

$$G_{\omega,x}(e) := \int_{\mathbb{R}} \frac{d\mu_x^\omega(\lambda)}{(e - \lambda)^2} = \lim_{\epsilon \downarrow 0} \|(\Delta + V_\omega - e - i\epsilon)^{-1} \delta_x\|^2.$$

By the Theorem of de la Vallé Poussin,

$$d\mu_{x,\text{ac}}^\omega(e) = \pi^{-1} \left( \lim_{\epsilon \downarrow 0} \epsilon \|(\Delta + V_\omega - e - i\epsilon)^{-1} \delta_x\|^2 \right) de.$$

Hence, if for a fixed  $\omega \in \Omega$  we have that  $G_{\omega,x}(e) < \infty$  for  $m$ -a.e.  $e \in \mathbb{R}$ , then  $\mu_{x,\text{ac}}^\omega = 0$ .

The Simon-Wolff localization criterion is summarized in:

**Theorem 3.3.** *Assume that  $\mathbb{P}$  has a conditional density along the  $x$ 'th coordinate. Let  $B \subset \mathbb{R}$  be a Borel set such that  $G_{\omega,x}(e) < \infty$  for  $\mathbb{P} \otimes m$ -a.e.  $(\omega, e) \in \Omega \times B$ . Then  $\mu_{x,\text{cont}}^\omega(B) = 0$  for  $\mathbb{P}$ -a.e.  $\omega \in \Omega$ .*

Theorem 3.3 is a well known consequence of the rank-1 Simon-Wolff theorem [SW] and the conditional Fubini theorem.

*Proof of Theorem 1.4.* Fix  $\omega \in \Omega$  and fix  $e \in \mathbb{R} \setminus \sigma_\omega$  for which the bound (3.4) holds. By monotone convergence

$$\int_{\mathbb{R}} \frac{d\mu_x^\omega(\lambda)}{(e - \lambda)^2} = \lim_{\epsilon \downarrow 0} \int_{\mathbb{R}} \frac{d\mu_x^\omega(\lambda)}{(e - \lambda)^2 + \epsilon^2} = \sup_{\epsilon > 0} \int_{\mathbb{R}} \frac{d\mu_x^\omega(\lambda)}{(e - \lambda)^2 + \epsilon^2}.$$

Since for any  $z \in \mathbb{C} \setminus \mathbb{R}$ ,

$$\lim_{r \rightarrow \infty} \| (H_{\omega,r} - z)^{-1} - (H_\omega - z)^{-1} \| = 0,$$

we have that the weak-\* limit  $\lim_{r \rightarrow \infty} \mu_{x,r}^\omega$  equals  $\mu_x^\omega$ , where  $\mu_{x,r}^\omega$  is the spectral measure for  $H_{\omega,r}$  and  $\delta_x$ . Therefore

$$\begin{aligned} \int_{\mathbb{R}} \frac{d\mu_x^\omega(\lambda)}{(e - \lambda)^2} &= \sup_{\epsilon > 0} \lim_{r \rightarrow \infty} \int_{\mathbb{R}} \frac{d\mu_{x,r}^\omega(\lambda)}{(e - \lambda)^2 + \epsilon^2} \leq \sup_{\epsilon > 0, r \geq 1} \int_{\mathbb{R}} \frac{d\mu_{x,r}^\omega(\lambda)}{(e - \lambda)^2 + \epsilon^2} \\ &= \sup_{r \geq 1} \int_{\mathbb{R}} \frac{d\mu_{x,r}^\omega(\lambda)}{(e - \lambda)^2} \\ &= \sup_{r \geq 1} \| (H_{\omega,r} - e)^{-1} \delta_x \|^2 \\ &= \sup_{r \geq 1} \sum_{y \in X} |G_{\omega,r}(x, y)|^2 < \infty. \end{aligned}$$

In the final equality we used the fact that  $\{\delta_y : y \in X\}$  is an orthonormal basis for  $l^2(X)$ . Since  $m(\sigma_\omega) = 0$  and since the bound (3.4) holds for  $m$ -a.e.  $e \in \mathbb{R} \setminus \sigma_\omega$ , we have that for every fixed  $\omega \in \Omega$ ,  $G_{\omega,x}(e) < \infty$  for  $m$ -a.e.  $e \in \mathbb{R}$ . This proves part (1). Part (2) follows from the fact that  $G_{\omega,x}(e) < \infty$  for  $\mathbb{P} \otimes m$ -a.e.  $(\omega, e) \in \Omega \times \mathbb{R}$  and the Simon-Wolff criterion.  $\square$

**Acknowledgements.** We are grateful to Professor Vojkan Jaksic, who suggested this research project, and from whom the author learned about random Schrödinger operators. We would like to thank Professor Stanislav Molchanov for

very helpful discussions and encouragements during the author's visit at the University of Charlotte, NC. We also benefited from discussions with the following people: Kingwood Chen, Serguei Denissov, Marco Merkli, Juan-Manuel Perez-Abarca and Nicola Squartini. A very special thank goes to Kingwood Chen for hospitality during the author's visit at UNCC.
